二、糖酵解过程概述

In the first five steps of glycolysis, the 6-carbon molecule of glucose is split into two 3-carbon compounds.

2 molecules of ATP are required to prime these reactions.

D-Glucose-6-phosphate (G6P)

Phosphoglucose isomerase

D-Fructose-6-phosphate (F6P)

D-Fructose-1,6-bisphosphate (FBP)

Aldol cleavage

Fructose biphosphate aldolase

Dihydroxyacetone phosphate (DHAP)

D-Glyceraldehyde-3-phosphate (G3P)

Triose phosphate isomerase

四、糖酵解第一阶段的反应机制

(一) 葡萄糖的磷酸化

磷酸果糖激酶是关键的调控酶，有4个亚基，3种同工酶，同工酶A存在于骨骼肌和心肌，对磷酸肌酸、柠檬酸、无机磷酸的抑制作用最敏感；同工酶B存在于肝脏和红细胞，对2,3-二磷酸甘油酸（BPG）的抑制作用最敏感；同工酶C存在于脑中，对腺嘌呤核苷酸的作用最敏感。

磷酸果糖激酶催化的反应不可逆，ATP是别构抑制剂，F-2,6-BP是别构激活剂。两次磷酸化使葡萄糖转化为反应活性很高的F-1,6-BP，有利于随后的分解反应。

(四) 果糖-1, 6-二磷酸转变为甘油醛-3-磷酸和二羟丙酮磷酸

高参考价值的真题、答案、学长笔记、辅导班课程，访问

醛缩酶有多种同工酶，

型醛缩酶存在于高等动植物，为四聚体，有3种同工酶，A主要存在于肌肉中，B主要存在于肝脏，C主要存在于脑组织，3种同工酶均由4中不同的亚基组成。

型醛缩酶存在于微生物，相对分子质量只有 型醛缩酶的一半，含有二价金属离子。

(五) 二羟丙酮磷酸转变为甘油醛-3-磷酸

二羟丙酮磷酸酶催化二羟丙酮磷酸转变为单体的结构，红色为二羟丙酮磷酸。

反应机制

In the first phase of glycolysis, glucose is converted to pyruvate.

In the second phase of glycolysis, glyceraldehyde-3-phosphate is converted to pyruvate.

These reactions yield 4 molecules of ATP, 2 for each molecule of pyruvate produced.

八、柠檬酸循环的发现历史

1937年Hans Krebs 提出柠檬酸循环的反应机制, 其主要的依据有: Krebs 于1932年发现乙酸, 琥珀酸, 延胡索酸, 苹果酸, 柠檬酸, 草酰乙酸可以促进组织匀浆或切片的氧化作用; Albert Szent-Gyorgyi发现少量的四碳二羧酸可以加快糖类氧化反应的速度, 提出可能存在于一个酶促的系列反应。他还发现了丙二酸对琥珀酸脱氢酶的抑制作用; Carl Martius 和Franz Knoop发现柠檬酸可以转化为图示的其他有机酸; Krebs发现草酰乙酸可以和活性乙酸反应生成柠檬酸, 在反映体系中过量加入其中的任意一种有机酸可以很快转化为其他的有机酸, 因而提出反应体系构成一个循环。

FIGURE 19-9 NADH:ubiquinone oxidoreductase (Complex I). Complex I catalyzes the transfer of a hydride ion from NADH to FMN, from which two electrons pass through a series of Fe-S centers to the iron-sulfur protein N-2 in the matrix arm of the complex. Electron transfer from N-2 to ubiquinone on the membrane arm forms QH₂, which diffuses into the lipid bilayer. This electron transfer also drives the expulsion from the matrix of four protons per pair of electrons. The detailed mechanism that couples electron and proton transfer in Complex I is not yet known, but probably involves a Q cycle similar to that in Complex III in which QH₂ participates twice per electron pair (see Fig. 19-12). Proton flux produces an electrochemical potential across the inner mitochondrial membrane (N side negative, P side positive), which conserves the energy released by the exergonic reactions. This electrochemical potential drives ATP synthesis.

复合体的电子传递途径

FIGURE 19-10 Structure of Complex II (succinate dehydrogenase) of *E. coli* (PDB ID 1NEK). The enzyme has two transmembrane subunits, C (green) and D (blue); the cytoplasmic extensions contain subunits B (orange) and A (purple). Just behind the FAD in subunit A (gold) is the binding site for succinate (occupied in this crystal structure by the inhibitor oxaloacetate, green). Subunit B has three sets of Fe-S centers (yellow and red); ubiquinone (yellow) is bound to subunit C; and heme *b* (purple) is sandwiched between subunits C and D. A cardiolipin molecule is so tightly bound to subunit C that it shows up in the crystal structure (gray spacefilling). Electrons move (blue arrows) from succinate to FAD, then through the three Fe-S centers to ubiquinone. The heme *b* is not on the main path of electron transfer but protects against the formation of reactive oxygen species (ROS) by electrons that go astray.

FIGURE 19-11 Cytochrome bc_1 complex (Complex III). The complex is a dimer of identical monomers, each with 11 different subunits. (a) Structure of a monomer. The functional core is three subunits: cytochrome b (green) with its two hemes (b_H and b_L , light red); the Rieske iron-sulfur protein (purple) with its 2Fe-2S centers (yellow); and cytochrome c_1 (blue) with its heme (red) (PDB ID 1BGY). (b) The dimeric functional unit. Cytochrome c_1 and the Rieske iron-sulfur protein project from the P surface and can interact with cytochrome c (not part of the functional complex) in the intermembrane space. The complex has two distinct binding sites for ubiquinone, Q_N and Q_P , which correspond to the sites of inhibition by two drugs that block oxidative phosphorylation. Antimycin A, which blocks electron flow from heme b_H to Q_P , binds to the P side of the membrane. Myxothiazol, which prevents electron flow from

QH_2 to the Rieske iron-sulfur protein, binds at Q_P , near the 2Fe-2S center and heme b_L on the P side. The dimeric structure is essential to the function of Complex III. The interface between monomers forms two pockets, each containing a Q_P site from one monomer and a Q_N site from the other. The ubiquinone intermediates move within these sheltered pockets.

Complex III crystallizes in two distinct conformations (not shown). In one, the Rieske Fe-S center is close to its electron acceptor, the heme of cytochrome c_1 , but relatively distant from cytochrome b and the QH_2 -binding site at which the Rieske Fe-S center receives electrons. In the other, the Fe-S center has moved away from cytochrome c_1 and toward cytochrome b . The Rieske protein is thought to oscillate between these two conformations, then oxidized.

FIGURE 19-12 The Q cycle. The path of electrons through Complex III is shown by blue arrows. On the P side of the membrane, two molecules of QH₂ are oxidized to Q, releasing four protons (two protons per Q (four protons in all) into the intermembrane space. Each

QH₂ donates one electron (via the Rieske Fe-S center) to cytochrome c₁, and one electron (via cytochrome b) to a molecule of Q near the P side, reducing it to QH₂. This reduction also uses two protons per Q, which are taken up from the matrix.

复合体IV的结构

FIGURE 19-13 Critical subunits of cytochrome oxidase (Complex IV). The bovine complex is shown here (PDB ID 1OCC). (a) The core of Complex IV, with three subunits. Subunit I (yellow) has two heme groups, a and a_3 (red), and a copper ion, Cu_B (green sphere). Heme a_3 and Cu_B form a binuclear Fe-Cu center. Subunit II (blue) contains two Cu ions (green spheres) complexed with the $-SH$ groups of two Cys residues in a binuclear center, Cu_A , that resembles the 2Fe-2S centers of iron-sulfur proteins. This binuclear center and the cytochrome

c -binding site are located in a domain of subunit II that protrudes from the P side of the inner membrane (into the intermembrane space). Subunit III (green) seems to be essential for Complex IV function, but its role is not well understood. (b) The binuclear center of Cu_A . The Cu ions (green spheres) share electrons equally. When the center is reduced they have the formal charges $Cu^{1+}Cu^{1+}$; when oxidized, $Cu^{1.5+}Cu^{1.5+}$. Ligands around the Cu ions include two His (dark blue), two Cys (yellow), an Asp (red), and Met (orange) residues.

复合体IV的电子传递

FIGURE 19-14 Path of electrons through Complex IV. The three proteins critical to electron flow are subunits I, II, and III. The larger green structure includes the other ten proteins in the complex. Electron transfer through Complex IV begins when two molecules of reduced cytochrome c (top) each donate an electron to the binuclear center Cu_A . From here electrons pass through heme a to the Fe-Cu center (cytochrome a_3 and Cu_B). Oxygen now binds to heme a_3 and is reduced to its peroxy derivative (O_2^{2-}) by two electrons from the Fe-Cu center. Delivery of two more electrons from cytochrome c (making four electrons in all) converts the O_2^{2-} to two molecules of water, with consumption of four "substrate" protons from the matrix. At the same time, four more protons are pumped from the matrix by an as yet unknown mechanism.

(四) ATP 合成机制

A model of the F_1 and F_0 components of the ATP synthase, a rotation molecular motor. The a, b, α, β , and δ subunits constitute the stator of the motor, and the c, γ , and ϵ subunits form the rotor. Flow of protons through the structure turns the rotor and drive the cycle of conformation changes in α and β that synthesize ATP.

The binding change mechanism for ATP synthesis by ATP synthase

实验证明3个质子通过离子通道可以合成一个ATP

FIGURE 19-24 Binding-change model for ATP synthase. The F₁ complex has three nonequivalent adenine nucleotide-binding sites, one for each pair of α and β subunits. At any given moment, one of these sites is in the β -ATP conformation (which binds ATP tightly), a second is in the β -ADP (loose-binding) conformation, and a third is in the β -empty (very-loose-binding) conformation. The proton-motive force causes rotation of the central shaft—the γ subunit, shown as a green arrowhead—which comes into contact with each $\alpha\beta$ subunit pair in succession. This produces a cooperative conformational change in which the β -ATP site is converted to the β -empty conformation, and ATP dissociates; the β -ADP site is converted to the β -ATP conformation, which promotes condensation of bound ADP + P_i to form ATP; and the β -empty site becomes a β -ADP site, which loosely binds ADP + P_i entering from the solvent. This model, based on experimental findings, requires that at least two of the three catalytic sites alternate in activity; ATP cannot be released from one site unless and until ADP and P_i are bound at the other.

FIGURE 19-18 Coupling of electron transfer and ATP synthesis in mitochondria. In experiments to demonstrate coupling, mitochondria are suspended in a buffered medium and an O_2 electrode monitors O_2 consumption. At intervals, samples are removed and assayed for the presence of ATP. (a) Addition of ADP and P_i alone results in little or no increase in either respiration (O_2 consumption; black) or ATP synthesis (red). When succinate is added, respiration begins immediately and

ATP is synthesized. Addition of cyanide (CN^-), which blocks electron transfer between cytochrome oxidase and O_2 , inhibits both respiration and ATP synthesis. (b) Mitochondria provided with succinate respire and synthesize ATP only when ADP and P_i are added. Subsequent addition of venturicidin or oligomycin, inhibitors of ATP synthase, blocks both ATP synthesis and respiration. Dinitrophenol (DNP) is an uncoupler, allowing respiration to continue without ATP synthesis.

(九) 氧的不完全还原

氧的彻底还原需要4个电子，1个电子使氧还原成超氧化物负离子，2个电子使氧还原成过氧化氢，3个电子使氧还原成羟自由基。

超氧化物歧化酶可清除超氧化物自由基，可能的机制如图24-33所示。

过氧化氢可被过氧化氢酶或谷胱甘肽过氧化物酶清除。

清除超氧化物自由基和过氧化氢可防止羟自由基的生成。

抗氧化剂有助于预防疾病和延缓衰老。
